### Abstract

Declining and fluctuating enrollments of the last decade have necessitated changes in the sizes and locations of schools in hundreds of districts across the United States. School administrators are thus faced with the difficult and complex problems of redistricting, compounded when desegregation is at issue. Researchers have worked for two decades with variants of a linear programming districting model which minimizes total distance traveled as all students are assigned to schools that are subject to capacity and racial balance limitations. This model could aid in the construction of districting alternatives but, in practice, is difficult to solve with generalized solution methods due to excessive size. Network-based representations have been actively pursued because of the existence of fast special algorithms and codes. However, single-network representations have been successful in modeling only special cases of this problem. We present here a generalized network flow problem with side constraints which is a new

and exact equivalent of this classic districting problem.
