Abstract

The steam reforming of ethanol on 5% Rh/Al₂O₃ catalyst has been investigated to produce H₂ adequate to feed a molten carbonate fuel cell (MCFC). The influence of reaction temperature, H₂O/EtOH molar ratio, gas hourly space velocities (GHSV) and O₂ were investigated in order to maximize the hydrogen content at the outlet of ethanol reformer. Endurance tests to assess the feasibility of a FC system fed by simulated bio-EtOH stream (H₂O/EtOH molar ratio=8.4) were also performed. Experiments carried out at MCFC operative conditions allowed to obtain a H₂ reach mixture close to 60% on dry basis. In steam reforming (SR) conditions an extensive formation of *encapsulated carbon* was registered while a great benefits, both in terms of catalyst stability and coke formation were evidenced adding 0.4 vol.% of oxygen in the reaction stream. Oxygen however promoted metal sintering. Consideration on

reaction mechanism, mainly investigated to distinguish the reaction pathway influencing the H₂ production, is reported.
