### Abstract

*Leptospira interrogans* serovars *pomona*, *hardjo* and *tarassovi* were each used to inoculate 6 cattle. Three-hundred and ninety-nine sera collected from the inoculated animals and from a control group over a 3-month period were tested using the microscopic agglutination test (MAT) and the enzyme-linked immunosorbent assay (ELISA). Leptospiuria was monitored by microscopic examination and culture. The ELISA detected specific IgM antibody against the serovars in all infected cattle 1 week after inoculation. This IgM antibody persisted in most of the animals for 3–5 weeks. Specific IgG antibody appeared at the same time or just after IgM, but persisted for much

longer. Levels of antibody detected by the ELISA and the MAT did not correlate with each other, nor with the periods of leptospiuria found in the infected cattle.
