### Publisher Summary

African swine fever (ASF) is a tickborne and contagious disease of swine, caused by a large icosahedral cytoplasmic DNA virus, which has been tentatively classified as an *Iridovirus*. ASF was first described in a comprehensive report by Montgomery in 1921. In this report he described the outbreaks of the disease in Kenya between 1909 and 1915 where 1352 (98.9%) of 1366 infected pigs died. In addition, he reported that the disease was caused by a virus, and reported the results of studies on transmission, virus survival in the environment, and host range, including the possible role of wild pigs in maintaining the virus in nature. He believed that the disease was caused by a serologic variant of the hog cholera virus (classical swine fever) a conclusion that was repeated in recent times when ASF was introduced into a previously uninfected area. Subsequent to Montgomery's report, ASF was diagnosed in many areas of southern Africa. In 1933, in an outbreak in South Africa, 8% of 11,000 infected pigs survived.
