Abstract

The forms and vibrational modes of church bells, carillon bells and handbells are discussed and compared. When the principal modes are classified in groups according to the numbers and locations of the nodal circles and meridians, the vibrational behaviours of church bells and carillon bells show similarities to those of the much smaller handbells. The different timbres are traced to the differences in the vibrational behaviour and the resulting spectra of partial tones. A subjective strike note, heard in the sound of church bells and carillon bells, does not appear in handbell sound, but a prominent octave partial in handbell sound is radiated indirectly by the fundamental mode of vibration. Modal frequencies in all three types of bells can be fitted to a suitably modified form of Chladni's law. Large church bells and carillon bells follow a $1/f$ scaling law; small carillon bells scale as $f \propto 1/n$, where n is slightly less than 1. In handbell sets, n may vary from about

12 in the larger bells to

12 in the smallest bells
